

Write a C++ program to overload the discount() function for calculating discounts with two and three parameters.

```
#include <iostream>
using namespace std;

float discount(float price, int rate)
{
    return price * rate / 100;
}

float discount(float price, int rate, int quantity)
{
    return (price * quantity) * rate / 100;
}

int main()
{
    float price;
    int rate, quantity;

    cout << "Enter price: ";
    cin >> price;

    cout << "Enter discount rate: ";
    cin >> rate;

    cout << "Discount = " << discount(price, rate) << endl;

    cout << "Enter quantity: ";
    cin >> quantity;

    cout << "Total Discount = "
        << discount(price, rate, quantity) << endl;

    return 0;
}
```

OUTPUT

```
Enter price: 2000
Enter discount rate: 30
Discount = 600
Enter quantity: 1
Total Discount = 600
```
